Structural HTML Corrections

The initial html pages had mostly correct structures, it had several critical syntax errors that caused modern browsers to render elements unpredictably. The following corrections were made without changing any of content, links, or image :

- **Corrected the <head> and <main> Tag Confusion:** In the original code, the <main> tag which has the page's content was nested inside a <head> tag. The <head> tag is meant for invisible background data such as titles and links to stylesheets. This was separated so <head> handles the settings, and <main> wraps your page content.
- **Corrected Nested Block Elements inside Paragraphs (<p>):** In HTML, a paragraph tag <p> cannot contain layout blocks like headers (<h2>), lists (), or large structural <div> elements.
- On the **Contact Us** page, the structural elements and image were accidentally trapped inside the first physical address <p> tag. This was broken up into clean, dedicated text containers.
- **Fixed Typos in Attributes:** Corrected instances where code was broken due to simple spelling slips, such as `tyle="flex: 1;"` being updated to the proper `class=""` selectors.
- **Standardized Line Breaks:** Replaced all occurrences of the invalid backward break tag </br> with the universally valid
 self-closing tag.
- **Organized Closing Tags:** Repaired multi-layered containers that were closing out of logical order, which prevents columns from overlapping or collapsing on mobile screens.

Explanation of the CSS Styles & Layout Layouts

The new external style.css file use modern layout design to replace the inline styles, making it look more cleaner and leading to a lighter to load.

Layout Mechanics: Flexbox

Instead of relying on rigid, screen-breaking inline parameters, the structure now uses **CSS Flexbox** (`display: flex;`).

- **The Navigation & Banner:** Flexbox separates the church logo to the left and the title text to the right seamlessly, adjusting smoothly regardless of how wide a user's web browser is.
- **The Content Cards:** The church branches, devotions, and contact info use `display: flex; gap: 20px; align-items: center;`. This splits the card into two perfect columns—text content on one side, images on the other—with a clean 20px gap between them.

Card Styling & Polish

To give the webpages a more polished, modern look, the cards use three combined properties being `border-radius: 10px`; to give the sharp container corners a soft, approachable curve, `border-left: 5px solid var(--color-accent)`; to place that beautiful signature green accent bar on the left edge of every container block `box-shadow: 0 2px 6px rgba(0, 0, 0, 0.08)`; to add a subtle shadow beneath the cards, giving them depth and making them look like they are cleanly floating above the background.

How the CSS Variables Work (:root)

The most powerful addition to the webpages is the introduction of **CSS Variables** defined at the top of the stylesheet inside the `:root` selector known as universal shortcuts instead of typing out `#1D9E75` or `#106554` fifty times across the code.

The Benefits of adding the CSS code:

- **Global Theme Control:** If a church administrator asks to change the background color of the *entire website* tomorrow, you do not have to open every HTML page or search through hundreds of lines of style code. They can simply change one colour code inside the `:root` block, and the background shifts instantly across all connected pages.
- **Typography Control:** Font definitions are centralized under variables like `--font-heading` and `--font-body`. If you want to transition your layout fonts to a cleaner sans-serif style later on, a single adjustment handles it perfectly.
- **Code Reusability:** Every page you create from now on (Home, About Us, Directory) can link to this exact same `style.css` file, ensuring perfect design harmony across your entire system.
